

# Data Mining Tasks

异常

# Anomaly/Outlier Detection

- What are anomalies/outliers?
  - The set of data points that are **considerably different** than the remainder of the data
- Given a database  $D$ , find all the data points  $\mathbf{x} \in D$  with **anomaly scores greater** than some threshold  $t$
- Applications:
  - Credit card fraud detection, fault detection, telecommunication fraud detection, network intrusion detection, ...

# Beyond Outliers

---

- Outliers are different from the **noise data**
  - Noise is random error
  - Noise should be removed before outlier detection
- Outliers are interesting: they violate the mechanism that generates the normal data
- Outlier detection vs. **novelty detection**: early stage, outlier; but later merged into the model

# Anomaly Detection

---

- Challenges
  - Method is **unsupervised**
    - Validation can be quite challenging
      - just like for clustering
  - **How many** outliers are there in the data?
    - Finding needle in a haystack
- Working assumption:
  - There are considerably **more** "normal" observations than "abnormal" observations (outliers/anomalies)

# Anomaly Detection Schemes

---

- Build a **profile** of the “normal” behavior
- Use the “normal” profile to **detect** anomalies
  - Anomalies are observations whose characteristics **differ significantly** from the normal profile

# Kinds of Outliers

---

- Global Outliers
- Contextual Outliers
- Collective Outliers

# Global Outlier

---

- **Global outlier** (or point anomaly)
  - Object is  $O_g$  if it significantly **deviates** from the rest of the data set
  - E.g.: Intrusion detection in computer networks
  - Issue: Find an appropriate measurement of deviation

# Contextual Outlier

---

- **Contextual outlier** (or *conditional outlier*)
  - Object is  $O_c$  if it deviates significantly based on a **selected context**
  - Ex. 40°C: outlier?
  - Attributes of data objects should be divided into two groups
    - **Contextual attributes**: defines the context, e.g., time & location
    - **Behavioral attributes**: characteristics of the object, used in outlier evaluation, e.g., temperature

# Collective Outliers

---

- **Collective Outliers**

- A subset of data objects *collectively* deviate significantly from the whole data set, even if the individual data objects may not be outliers
- Applications: E.g., *intrusion detection*:
  - When a number of computers keep sending denial-of-service packages

# Anomaly Detection Schemes

---

- Types of anomaly detection schemes
  1. Statistical-based
  2. Proximity-based
  3. Cluster-based

# Statistical Schemes

---

- Statistical approaches assume that the objects in a data set are generated by a stochastic process (a **generative model**)
- Idea: **learn** a generative model fitting the given data set, and then identify the objects in **low probability** regions of the model as outliers
- Methods are divided into two categories:
  - Parametric 参数的
  - Non-parametric

# Statistical Schemes - Parametric

- Assume a **parametric model** describing the distribution of the data
  - Example: normal distribution
- Apply a statistical test that depends on
  - Data distribution
  - Parameter of distribution (e.g., mean, variance)
  - Number of expected outliers (**confidence limit**)

# Example

---

- Ex: Avg. temp.: {24.0, 28.9, 28.9, 29.0, 29.1, 29.1, 29.2, 29.2, 29.3, 29.4}
- Use the maximum likelihood method to estimate  $\mu$  and  $\sigma$
- Taking derivatives with respect to  $\mu$  and  $\sigma^2$ , we derive the following maximum likelihood estimates

$$\hat{\mu} = \bar{x} = \frac{1}{n} \sum_{i=1}^n x_i \quad \hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2$$

- For the above data with  $n = 10$ , we have  $\hat{\mu} = 28.61$   $\hat{\sigma} = \sqrt{2.29} = 1.51$
- Then  $|24 - 28.61| / 1.51 = 3.04 > 3$ , 24 is an outlier since  $\mu \pm 3\sigma$  region contains 99.7% data

1..68%  
2..95%  
3 . . 99%

# Limitations of Parametric Schemes

---

- In many cases, data distribution **may not be known**
- Most of the tests are for a **single attribute**
  - For **high dimensional data**, it may be difficult to estimate the true distribution

# Statistical Schemes – Non-Parametric

---

- The model of normal data is **learned** from the input data without any a priori structure.
- Often makes fewer assumptions about the data, and thus can be applicable in more scenarios
- Outlier detection using **histogram**

# Example

- Figure shows the histogram of purchase amounts in transactions
- A transaction in the amount of \$7,500 is an outlier:
  - only 0.2% transactions have an amount higher than \$5,000

# Histogram Challenge

---

- Problem: Hard to choose an appropriate bin size for histograms
- Too small bin size:
  - normal objects in empty/rare bins: false positive
- Too big bin size:
  - outliers in some frequent bins: false negative

# Anomaly Detection Schemes

---

- Types of anomaly detection schemes
  1. Statistical-based
  2. Proximity-based
  3. Cluster-based

## Distance-Based Schemes

---

- An object is an outlier if **the nearest neighbors of the object are far away**
  - the **proximity** of the object **significantly deviates** from the proximity of **most of the other objects in the same data set**
- **Example:** Model the proximity of an object using its **3** nearest neighbors
  - Objects in region **R** are substantially different from other objects in the data set.
  - Thus the objects in **R** are **outliers**

## Distance-Based vs. Density-Based Outlier Detection

---

- Two types of proximity-based outlier detection methods
  - **Distance-based outlier detection:**
    - An object  $\bullet$  is an outlier if its **neighborhood** does not have enough other points
  - **Density-based outlier detection:**
    - An object  $\bullet$  is an outlier if its **density** is relatively much lower than that of its neighbors

# Distance-Based Outlier Detection

---

- For each object  $o$ ,
  - examine the **number** of other objects in the  **$r$ -neighborhood** of  $o$ 
    - $r$  is a user-specified **distance threshold**
  - an object  $o$  is an outlier if
    - **most** of the objects in  $D$  are far away from  $o$  (i.e., not in the  $r$ -neighborhood of  $o$ )

# Distance-Based Outlier Detection

- An object  $o$  is a **DB( $r, \pi$ )** outlier if 
$$\frac{|\{o' | \text{dist}(o, o') \leq r\}|}{|D|} \leq \pi$$

where  $\pi$  is a **fraction threshold**

- Equivalently, one can check the distance between  $o$  and its  **$k$ -th nearest neighbor**  $o_k$

where  $k = \lceil \pi |D| \rceil$

$o$  is an outlier if  $\text{dist}(o, o_k) > r$

# Computation

- Efficient computation: **Nested loop algorithm**
- For any object  $o_i$ :
  1. calculate its distance from other objects, and
  2. count the number of objects in its  $r$ -neighborhood.
- If  $\pi D$  other objects are within  $r$  distance, then terminate the inner loop
- Else,  $o_i$  is a  $DB(r, \pi)$  outlier
- Efficiency: Actually CPU time is not  $O(n^2)$  but linear to the data set size since for most non-outlier objects, the inner loop terminates early

只要找到 距离大于 $r$ 的点的个数大于  $\pi D$ , 就会跳出循环

## Density-Based Outlier Detection

---

- **Local outliers:**

- Outliers compared to their **local neighborhoods**, instead of the **global** data distribution

- Example:  $o_1$  and  $o_2$  are **local outliers** to  $C_1$ ,  $o_3$  is a **global outlier**, but  $o_4$  is not an outlier.
- However, proximity-based clustering cannot find  $o_1$  and  $o_2$  are outliers

## Density-Based Outlier Detection

---

- **Intuition:**

- The **density** around an outlier object is **significantly different from** the density around its neighbors

- **Method:**

- Use the **relative** density of an object against its neighbors as the **indicator** of the degree of the object being an outlier

# Density-based: LOF approach

---

- For each point:
  - compute the density of its local neighborhood
- Compute **local outlier factor (LOF)** of a sample  $p$  as the average of:
  - the ratio of the density of sample  $p$  and the density of its nearest neighbors
- Outliers are points with lowest LOF value

# Density

---

- Several methods to measure the density of a point  $x$ 
  - Density =  $k$  / distance to the  $k$  nearest neighbors, or

$$\text{density}(x, k) = \left( \frac{\sum_{y \in N(x, k)} \text{distance}(x, y)}{|N(x, k)|} \right)^{-1}$$

Where  $N(x, K)$  is the set containing the  $k$  nearest neighbors of  $x$

# Density-based: LOF approach

In the **distance-based** approach:

- $p_2$  is not considered as outlier,
- LOF approach finds both  $p_1$  and  $p_2$  as outliers

## Proximity-Based Methods

---

- The effectiveness of proximity-based methods highly relies on the proximity measure
- In some applications, proximity or distance measures **cannot be obtained** easily
- Often have a difficulty in finding a group of outliers which **stay close to each other**

# Anomaly Detection Schemes

---

- Types of anomaly detection schemes
  1. Statistical-based
  2. Proximity-based
  3. Cluster-based

# Clustering-Based Methods

- **Normal** data belong to large and dense clusters
- An object is an outlier if:
  1. it does not belong to any cluster,
  2. there is a large distance between the object and its closest cluster , or
  3. it belongs to a small or sparse cluster
- Since there are many clustering methods, there are **many** clustering-based outlier detection methods as well

# Clustering-Based Methods

- Case 1: Far from its closest cluster
- Using k-means, partition data points of into clusters
- For each object  $o$ , assign an outlier score based on its distance from its closest center
  - If  $\text{dist}(o, c_o)/\text{avg\_dist}(c_o)$  is large, likely an outlier

# Clustering-Based Methods

---

- Case 2: Not belong to any cluster
- Identify animals not part of a flock:
  - Using a density-based clustering method such as DBSCAN

## Clustering-Based Method: limitations

---

- Effectiveness depends highly on the clustering method used
- High computational cost: Need to first find clusters
